Section 5. Direct Memory Access

High Speed and Direct Data Transfer Between Memory and Peripherals

Basic Concepts of DMA

- Limitations of Interrupt Processing
  - CPU involvements
  - Good for discrete events with small amount of data
  - Inefficient for large data transfers
- Needs for High Speed Data Transfer between
  - Disk and RAM;
  - NIC and RAM;
  - more
- An analogous example: Program of Study
  - Student asks dean for advising and signature ➔ Request
  - Dean directs student to the advisor ➔ address, tasks, and go
  - Student talks with the advisor ➔ communication/data transfer
  - Advisor signed the program of study after completing advising and send student back to dean for final signature ➔ report completion

General Procedure of DMA

- DMA Request
  - Request from peripheral through hardware
  - Explicit software initiation
  - Channel to channel linking for continual transfer
- Source/ Destination and amount of Data Transfer
  - CPU write registers in DMA controller to define
    - Source address, destination address, and byte count
- Direct and Continuous Data Transfer
  - Data transfer is done directly between memory and peripheral device without CPU involvement
- Report Completion
  - When transfer is done, reporting completion through interrupt

Introduction of DMAMUX

The DMA Mux routes up to 63 DMA sources (called slots) to be mapped to any of the 16 DMA channels. This is illustrated in the following figure.

Features and Modes of Operation

The DMA channel MUX provides these features:
- 52 peripheral slots + 10 always-on slots can be routed to 16 channels.
- 16 independently selectable DMA channel routers.
- The first 4 channels additionally provide a trigger functionality.
- Each channel router can be assigned to one of the 52 possible peripheral DMA slots or to one of the 10 always-on slots.

Operating modes:
- Disabled mode
  - The DMA channel is disabled, used mainly as the reset state for a DMA channel in the DMA channel MUX
- Normal mode
  - A DMA source (such as DSP transmit or DSP receive) is routed directly to the specified DMA channel.
- Periodic trigger mode
  - A DMA source may only request a DMA transfer (such as when a transmit buffer becomes empty or a receive buffer becomes full) periodically.

Channel Configuration Register (DMAMUXx_CHCFGn)

- Enable/Disabled and associated with DMA slots
Enabling and configuring sources

Enabling a source with periodic triggering

1. Determine with which DMA channel the source will be associated. Note that only the first 4 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] bits of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Configure the corresponding timer.
5. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] bits are set.

Example:

Configure source #5 transmit for use with DMA channel 2, with periodic triggering capability.

1. Write 0x00 to CHCFG2 (base address + 0x02).
2. Configure channel 2 in the DMA, including enabling the channel.
3. Configure a timer for the desired trigger interval.
4. Write 0xC5 to CHCFG2 (base address + 0x02).

The following code example illustrates steps #1 and #4 above:

```c
Enabling a source without periodic triggering

Enabling a source without periodic triggering

1. Determine with which DMA channel the source will be associated. Note that only the first 4 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] bits of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] is set while the CHCFG[TRIG] bit is cleared.

Disabling a source

A particular DMA source may be disabled by not writing the corresponding source value into any of the CHCFG registers.

Switching the source of a DMA channel

1. Disable the DMA channel in the DMA and re-configure the channel for the new source.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] bits of the DMA channel.
3. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] bits are set.

Example:

Switch DMA channel 8 from source #5 transmit to source #7 transmit.

1. In the DMA configuration registers, disable DMA channel 8 and re-configure it to handle the transfers to peripheral slot 7. This example assumes channel 8 doesn’t have triggering capability.
2. Write 0x00 to CHCFG8 (base address + 0x08).
3. Write 0x87 to CHCFG8 (base address + 0x08). (In this example, setting the CHCFG[TRIG] bit would have no effect, due to the assumption that channel 8 does not support the periodic triggering functionality.)

The following code example illustrates steps #2 and #3 above:

Example:

DMA Controller of K70

- All data movement via dual-address transfers, read from source, write to destination.
  - Programmable source and destination addresses and transfer size.
- Support for enhanced addressing modes.
- 32-channel implementation that performs complex data transfers with minimal intervention from a host processor.
  - Internal data buffer, used as temporary storage to support burst transfers.
- Connections to the crossbar switch for bus mastering the data movement.
- Transfer control descriptor (TCD) organized to support two-deep, nested transfer operations.
  - 32-byte TCD stored in local memory for each channel.
  - An inner data transfer loop defined by a minor byte transfer count.
  - An outer data transfer loop defined by a major iteration count.
- Channel activation via one of three methods:
  - Explicit software initiation.
  - Initiate via a channel-to-channel linking mechanism for continuous transfers.
  - Peripheral-paced hardware requests, one per channel.
- Fixed-priority and round-robin channel arbitration.
- Channel completion reported via optional interrupt requests.
  - One interrupt per channel, optionally enabled or disabled on a per-channel basis.
- Optional support for scatter/gather DMA processing.
- Support for complex data structures.
- Support to cancel transfers via software.
3 Segments Operation Procedure: 1st Channel Activation

2nd Data Transfer

3rd: Completion

Configurable DMA Registers

- TCDn: 32 transfer control descriptors, each has:
  - Source address: DMA_TCDn_SADDR, 32 bits
  - Signed Source Address Offset: DMA_TCDn_SOFF, 16 bits
  - Transfer Attributes: DMA_TCDn_ATTR, 16 bits
  - Minor Byte Count: DMA_TCDn_NBYTES_MLNO
  - Signed Minor Loop Offset: DMA_TCDn_NBYTES_MLOFFNO
  - Last Source Address Adjustment: DMA_TCDn_SLAST
  - Destination Address: DMA_TCDn_DADDR
  - Signed Destination Address Offset: DMA_TCDn_DOFF
  - Current Minor Loop Link, Major Loop Count: DMA_TCDn_CITER_ELINKNO
  - Last Destination Address Adjustment: DMA_TCDn_DLASTSGA
  - Control and Status Register: TCDn_CSR
  - Beginning Minor Loop Link, Major Loop Count: DMA_TCDn_BITER_ELINKYES

Example Registers of TCDn

- Control and Status Register
  - BWC: BW control:
    - 10: DMA stalls for 4 cycle after each R/W.
    - 11 stalls for 8 cycles
  - Bit 3 enables channel linking to MAJOR_LINKCH after Major Loop Counter is exhausted
  - Done [7]: completion flag
  - ACTIVE: signaling DMA active
  - Bits 1 and 2 enable IRQ when MLC done and half done, resp
  - START: writing a 1 to this bit explicitly start DMA

Transfer Attributes Register: ATTR

- Defines several different transfer attributes:
  - SMOD
    - 5 bits address modulo for implementing a circular queue buffer
    - Value here specifies 8 of lower order address bits that change
    - Src offset is typically set to the transfer size, post-increment
  - SSIZE
    - Source data transfer size: 0:8-bit, 1:16-bit, 2:32-bit, 4:16B
  - DMOD, DSIZE

To initialize the eDMA:

1. Write to the CR if a configuration other than the default is desired.
2. Write the channel priority levels to the DCHPRIn registers if a configuration other than the default is desired.
3. Enable error interrupts in the EEI register if so desired.
4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the ERQ register.
6. Request channel service via either:
   - Software: setting the TCDn_CSR[START]
   - Hardware: slave device asserting its eDMA peripheral request signal

Single Request Example:

This generates the following event sequence:

1. User writes to the TCDn_CSR[START] bit requests channel service.
2. The channel is selected by arbitration for servicing.
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
   - Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003
   - Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007
   - Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B
   - Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F
   - Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003
6. eDMA engine writes: TCDn_SADDR = 0x1000, TCDn_DADDR = 0x2000, TCDn_CITER = 1 (TCDn_BITER).
8. The channel retires and the eDMA goes idle or services the next channel.
